

FastAPI Dependencies

What is Dependency Injection?

Dependency Injection is a technique where an object receives the other objects it depends on, instead of creating them itself. In FastAPI, you declare a dependency using the `Depends()` function. FastAPI then calls that dependency for you and passes the result into your path operation function.

Why use it?

Dependency Injection helps you share logic such as database connections, authentication checks, and configuration across many endpoints without repeating code. It also makes testing easier because you can replace a real dependency with a fake one.

Example

You write a function that returns a database session, then add `Depends(get_db)` as a parameter. FastAPI runs `get_db` before your endpoint and injects the session. This is the core of how dependency injection works in FastAPI.
